# Variations of Lake Ice Phenology on the Tibetan Plateau from 2001 to 2017 Based on MODIS Data **a** (#) **b** Yu Cai, Chang-Qing Ke School of Geographic & Oceanographic Sciences, Nanjing University, 210023, China (caiyu13834585@163.com, kecq@nju.edu.cn)

## Introduction

There are about 1200 lakes (>1 km<sup>2</sup>) on the Tibetan Plateau (TP), and many studies have shown that lake ice phenology respond well to climatic and environmental changes. In the context of global climate change, lake ice phenology can be used as a good indicator to monitor the actual impact of climate change.

The MODIS daily snow products are used to extract the freeze-up and breakup dates of lake ice on the TP from 2001 to 2017. The lake ice durations are then calculated, and the spatial variabilities and change rates of lake ice phenology are analyzed. Using reanalysis data and available satellite dataset, the effects of air temperature, lake surface water temperature, and wind speed on lake ice phenology are analyzed. In addition, possible influence of lake locations and physico-chemical conditions on lake ice phenology are also investigated.

## **Data & Methods**

Fig. 1 Locations of the TP and its sub-basins. 58 study lakes are grouped into three sub-areas labeled Inner I, Inner II, and Other III.

Fig. 4 Mean and change rate of freeze-up start and break-up end dates of the 58 lakes from 2001 to 2017.

#### Fig. 5 Mean and change rate of ice cover duration for the 58 lakes from 2001 to 2017

## Cloud removal process:

- $S_{(A, output)} = water \text{ if } S_{(A, Aqua)} = water \text{ or } S_{(A, Terra)} = water$
- $S_{(A, output)} = cloud$  if  $S_{(A, Aqua)} = cloud$  and  $S_{(A, Terra)} = cloud$
- $S_{(A, t)} = water \text{ if } S_{(A, t-1)} = S_{(A, t+1)} = water$  $\bullet$
- $S_{(A, t-1)}, S_{(A, t)} = water \text{ if } S_{(A, t-2)} = S_{(A, t+1)} = water$
- $S_{(A, t)}, S_{(A, t+1)} = water \text{ if } S_{(A, t-1)} = S_{(A, t+2)} = water$

## Freeze-thaw dates extraction:

- $Th_h = 95\% \cdot M_h + 5\% \cdot M_l$
- $Th_1 = 5\% \cdot M_h + 95\% \cdot M_1$

Fig. 2 The extraction of the freeze-thaw dates in Qinghai Lake during 2013. Two red lines represent the two thresholds for extracting freeze-thaw dates, and four red stars, from left to right, represent the freeze-up start (FUS), freeze-up end (FUE), break-up start (BUS), and break-up end (BUE) dates.

## **Results & Analysis**

Table 1 Comparison of cloud cover for 58 lakes during 2013, with and without cloud removal.

	Mean	Maximum	Minimum
Original Terra	44.97%	63.98% (Taiyang Lake)	30.07% (Zhaxi Co)
Original Aqua	51.70%	69.43% (Taiyang Lake)	31.47% (Mapam Yumco)
Combined T&A	31.02%	50.94% (Taiyang Lake)	18.58% (Lagkor Co)
Cloud removal	16.54%	35.49% (Taiyang Lake)	4.52% (Zhari Namco)

Fig. 3 Comparison of lake water cover proportions derived from the MODIS cloud-removed data and Landsat data.

- > Approximately two-thirds of the cloud cover from the MODIS daily snow cover products can be removed by combining Terra and Aqua data and by using the pixels within 2 days.
- > Lakes on the TP begin to freeze-up in late October, and all the lakes enter the ice cover period in mid-January of the following year. In late March, some lakes begin to break-up, and all the lakes cease to be ice covered in early July. > Over 17 years, the mean ice cover duration of 58 lakes is 157.78 days, of which the ice cover durations of 18 lakes have extended by a mean rate of 1.11 d yr<sup>-1</sup>, and those of the other 40 lakes have shortened by a mean rate of 0.80 d yr<sup>-1</sup>.
- > The lakes in the northern Inner-TP have earlier freeze-up dates and later breakup dates (i.e. longer ice cover durations) than do the lakes in the southern Inner-TP.
- $\succ$  The geographical location and climate conditions determine the spatial heterogeneous of the lake ice phenology, especially the break-up dates, while the physico-chemical characteristics mainly affect the freeze-up dates of the lake ice.
